**Topic : Docker file : COPY . .**

---

**In Docker File : Command : COPY . .**

**( What is the concept ) :**

- This command is a way of saying like take everything from where I am now on my computer and put it into the current folder inside the container
- So the Source is your computer which is the HOST and the Destination is the inside of the container which is the image

**( Understanding the Syntax ) : COPY <source> <destination>**

- Basically source is where files come FROM local folder and destination is where all the files go TO inside the container

**( Understanding the command ) : COPY . .**

- Basically , a single dot ( . ) represents the current folder you are currently or standing in

**First this command has two parts :**

**First dot :**

- This is the source which means " from here " and also current folder on your computer
- This tells Docker to look at current folder on your computer where the docker file is located
- So this copies From your local project folder such as app1 folder

**Second dot :**

- This is the destination which means  “to here “ and also current folder inside the container
- This tells the docker to paste those files into the working folder inside the container
- So it copies everything into the /app folder inside the container such as WORKDIR /app

**How the working happens :**

YOUR COMPUTER (Source)  DOCKER CONTAINER (Destination)

myproject/  /

├── app1/  └── app/

│  ├── app.py  ├── app.py  ← from app1

│  ├── dockerfile  ├── dockerfile  ← from app1

│  ├── requirements.txt  ├── requirements.txt ← from app1

├── app2/

│  ├── app.py  ❌ NOT COPIED (Since you're building app1)

│  ├── dockerfile  ❌ NOT COPIED

│  ├── requirements.txt  ❌ NOT COPIED

└── docker-compose.yml  ❌ NOT COPIED

**So when you run docker build from inside the app1 folder :**

- Your current directory : /Users/you/myproject/app1 copies from app1 folder to /app in container using COPY . .
- So it does not copy app2 because they are outside app1

**When we run this command :**

- cd /Users/you/myproject/app1
- docker build .

**By using COPY . . which means :**

- FROM : /Users/you/myproject/app1/ ( Everything in app1 folder )
- TO : /app/ ( Inside container )

**So :**

- FROM app1/app.py copies TO /app/app.py
- FROM app1/dockerfile copies TO /app/dockerfile
- FROM app1/requirements.txt copies TO /app/requirements.txt

**Basically , COPY . .**

- Known as COPY FROM TO

Using COPY . .

- From source which is our local folder such as myproject/app1/
- To destination which is the container folder /app/

**So therefore ,**

- COPY is the command to move files
- First ( . ) dot means current local folder : /app1/
- Second ( . ) dot means current container folder : /app/
